INTRODUCTION

Sample costs to produce baby lima beans in the northern San Joaquin Valley are shown in this study. The study is intended as a guide only, and can be used to make production decisions, determine potential returns, prepare budgets and evaluate production loans. The practices described are based on production operations considered typical for this crop and region, but will not apply to every farm. Sample costs for labor, materials, equipment and custom services are based on current figures. “Your Costs” columns in Tables 1 and 2 are provided for entering your farm costs.

The hypothetical farm operations, production practices, overhead, and calculations are described under the assumptions. For additional information or an explanation of the calculations used in the study call the Department of Agricultural and Resource Economics, University of California, Davis, California, (530) 752-3589 or the local UC Cooperative Extension office.

Current and archived Sample Cost of Production Studies for many commodities can be downloaded at <http://coststudies.ucdavis.edu>, requested through the Department of Agricultural and Resource Economics, UC Davis, (530) 752-6887 or obtained from the local county UC Cooperative Extension offices.

The University of California does not discriminate in any of its policies, procedures or practices. The university is an affirmative action/equal opportunity employer.

ASSUMPTIONS

The assumptions refer to Tables 1 through 7 and pertain to sample costs to produce baby lima beans in the northern San Joaquin Valley. The cultural practices described and materials used are considered typical for a well-managed bean field in the region. The costs, materials, and practices will not apply to all situations every production year. Cultural practices vary among growers within the region and can be significant. The study is intended as a guide only. **The use of trade names and cultural practices in this report does not constitute an endorsement or recommendation by the University of California nor is any criticism implied by omission of other similar products or cultural practices.**

Farm. This report is based on a 1,200 non-contiguous acre field and row crop farm on which 200 acres of rented land are producing baby lima beans; 1,000 acres of rented and grower owned land are planted to alfalfa hay, field corn, tomatoes, and wheat. The grower maintains an equipment yard and shop on a portion of the owned land.

Production Cultural Practices and Material Inputs

Land Preparation. Primary tillage, which includes subsoiling, discing, land leveling (laser and triplane), and listing beds is done from October through April. The land is subsoiled in two directions to open the soil structure and breakup any hardpan. The field is then disced three times to create an adequate seedbed, and leveled in two passes with a triplane. Although the fields are basically level, the fields are laser leveled once every four years and one-fourth of the cost is charged to the current bean crop. The beds are listed and preplant fertilizer applied by a custom operator/fertilizer company in a single operation. Herbicides are applied and the field is preirrigated prior to planting.

Plant. Several varieties of bush and vine baby limas are available for planting, but no specific variety is included in this study. Baby lima beans are planted from May to early June (June in this study) using a six-row bean planter. The seeds at 70 pounds per acre are planted two to four inches deep into moist soil on 30-inch beds and will emerge in seven to ten days depending on soil temperature. Planting costs include the seed, tractor driver and one attendant on the planter.

Irrigation. Irrigation includes the water costs and irrigation labor. Water at \$40 per acre foot (\$3.33 per acre inch) is assumed to be a typical cost. Water costs in the region range from \$5 to \$75 per acre-foot. Most growers use surface water and the cost will vary by water district. The beans are furrow irrigated with one pre-irrigation and four regular season irrigations from late June/early July to September. A total of 30 acre-inches of water, which includes the preplant irrigation, is applied. Ditches are made for the preirrigation, and then closed prior to planting. Ditches are made again after the cultivation and closed prior to harvest. Water is delivered from the ditches to the furrows by siphon pipes.

Fertilization. Nitrogen (N) recommendations range from 80 to 120 units per acre. All or part of the nitrogen requirement (as UN32, aqua ammonia, or anhydrous ammonia) is banded during listing using two shanks, 6-inches to each side of the seed row. Also during bed listing along with the nitrogen, 4-10-10 starter fertilizer at 209 pounds per acre (20 gallons) plus two quarts of zinc is banded two-inches below and two-inches to the side of the seed row. Additional nitrogen can be sidedressed once the beans have reached the three to four leaf stage. Although not included in the study, soil amendments with gypsum or sulfur products are a routine practice and may be necessary every three to four years.

Pest Management. The pesticides and rates mentioned in this cost study are listed in *UC Integrated Pest Management Guidelines, Beans*. For more information on other pesticides available, pest identification, monitoring, and management visit the above UC IPM website at www.ipm.ucdavis.edu. For information and pesticide use permits, contact the local county agricultural commissioner's office. **Pesticides mentioned in this study are used to calculate rates and costs. Although the pesticides mentioned are commonly used by growers, other pesticides are available. Check with your Farm Advisor, PCA and/or the UC IPM website for current recommendations.** Spray adjuvants are an additional cost and may be necessary for use with many pesticides for effective control. They are assumed to be included in the pesticide cost in this study. Pesticide costs vary by location, brand, and grower volume. Pesticide costs in this study are taken from a single dealer and shown as full retail.

Pest Control Adviser (PCA). Written recommendations are required for commercially applied pesticides and are written by licensed pest control advisers. In addition the PCA will monitor the field for other problems including pests, diseases, and nutritional status. Growers may hire private consultants or receive the service as part of an agreement with an agricultural chemical and fertilizer company. Separate costs for a PCA are not included in this study.

Weeds. Herbicides -- Dual Magnum and Treflan -- are applied preplant to the listed beds and furrows, then mixed in the soil with a rolling cultivator – the first pass applies and incorporates the herbicides (spray boom and cultivator attached to tractor); the second pass is for further incorporation. The beans are cultivated twice either in June and/or early July prior to row closure. Once the ditches are made, all turning is done inside the field.

Insects. The major insect pests are twospotted (*Tetranychus urticae*), strawberry (*Tetranychus turkestanii*) and pacific spider (*Tetranychus pacificus*) mites, lygus bugs (*Lygus hesperus*, *Lygus elisus*), black bean and cow pea aphid (*Aphis fabae*, *Aphis craccivora*). Comite miticide for mite control is applied in June/July after cultivation. Lygus bugs are controlled with an air application of an OP (organophosphate) insecticide (e.g. Dimethoate), during August bloom, and a pyrethroid insecticide (e.g. Warrior) later during pod fill. The Dimethoate application also controls aphid. Additional lygus control may be needed until pod maturity. Worm control may be needed in some years for corn earworms and armyworms to prevent bean seed damage in the pod. The ground (Comite) and air (Dimethoate/ Warrior) applications are done by a custom operator.

Diseases. Seedling diseases are caused by rhizoctonia (*Rhizoctonia solani*) and pythium (*Pythium* spp.) root rot, and are prevented using seed treatments and good cultural practices. The fungicide seed protectants are applied to the seed by the bean warehouse and the cost is included in the seed price.

Harvest. The beans are cut and threshed by a custom operator during September/October. At maturity six rows per pass are cut at ground level with a set of tractor-mounted knives. One to two days later, depending on bean moisture, the cut beans are raked into windrows consisting of six to eight rows. Lima beans are harvested using bean threshers equipped with two or three slow-turning cylinders. Beans are ready for harvest when they reach 12% moisture. Cutting and windrowing costs \$38 per acre. Threshing/harvesting costs \$2.50 per hundredweight (cwt) based on field/dirt weight plus \$0.70 cwt for hauling. Other postharvest bean costs include warehouse charges of \$3.00 per cwt for cleaning, storage and insurance.

Yields. The crop yield used in this study is 27 cwt field/dirt weight or 25 cwt per acre of cleaned beans at 12% moisture. A typical cleanout rate for field run beans is 5-10%.

Returns. Based on the 2008 and 2009 Bean Market Reports a price of \$50 per cwt is used to calculate income. Prices for baby lima beans during this period ranged from \$40 to \$61 per cwt. The prices are used to show a range of returns over a range of yield in The Ranging Analysis Table.

Assessments. The California Dry Bean Board (CDBB) assesses \$0.175 per hundredweight (cwt) to all bean varieties (general assessment). Additional assessments are made by varietal councils formed for specific research on that variety. The baby lima council assesses \$0.04 per cwt. The CDBB promotes marketing and research in dry beans.

Pickup/ATV. Costs for a 3/4-ton pickup and ATV are included in the study. The pickup and ATV may be used by the irrigator, field foreman and/or the grower. The pickup travels 9,000 miles per year (1,500 miles for the beans) and the ATV 3,000 miles per year (500 miles for the beans). The miles are not based on any actual data, but the assumptions are used to calculate a vehicle cost for this study.

Labor, Equipment and Interest

Labor. Labor rates of \$14.39 per hour for machine operators and \$11.65 for general labor includes payroll overhead of 37%. The basic hourly wages are \$10.50 for machine operators and \$8.50 for general labor. The overhead includes the employers' share of federal and California state payroll taxes, workers' compensation insurance for field crops (code 0171), and a percentage for other possible benefits. Workers' compensation costs will vary among growers. For this study the cost is based upon the average industry final rate as of January 1, 2010 (personal email from California Department of Insurance, March 2010). Labor for operations involving machinery are 20% higher than the operation time given in Table 1 to account for the extra labor involved in equipment set up, moving, maintenance, work breaks, and field repair.

Wages for management are not included as a cash cost. Any return above total costs is considered a return to management and risk. However, growers wanting to account for management may wish to add a fee. The manager makes all production decisions including cultural practices, action to be taken on pest management recommendations, and labor.

Equipment Operating Costs. Repair costs are based on purchase price, annual hours of use, total hours of life, and repair coefficients formulated by American Society of Agricultural Engineers (ASAE). Fuel and lubrication costs are also determined by ASAE equations based on maximum Power Take Off (PTO) horsepower, and fuel type. Prices for on-farm delivery of diesel and gasoline are \$2.04 and \$2.67 per gallon, respectively. The cost includes a 2.5% local sales tax on diesel fuel and 7.5% sales tax on gasoline. Gasoline also includes federal and state excise tax, which are refundable for on-farm use when filing your income tax. The fuel, lube, and repair cost per acre for each operation in Table 1 is determined by multiplying the total hourly operating cost in Table 6 for each piece of equipment used for the selected operation by the hours per acre. Tractor time is 10% higher than implement time for a given operation to account for setup, travel and down time. Fuel prices have fluctuated considerably and may be higher or lower on any given day.

Interest on Operating Capital. Interest on operating capital is based on cash operating costs and is calculated monthly until harvest at a nominal rate of 5.75% per year. A nominal interest rate is the typical market cost of borrowed funds. The interest cost of post harvest operations is discounted back to the last harvest month using a negative interest charge. The interest rate will vary depending upon various factors. The rate in this study is considered a typical lending rate by a farm lending agency as of January 2010.

Risk. Production risks should not be minimized. While this study makes every effort to model a production system based on typical, real world practices, it cannot fully represent financial, agronomic and market risks, which affect the profitability and economic viability of bean production.

Cash Overhead

Cash overhead consists of various cash expenses paid out during the year that are assigned to the whole farm and not to a particular operation.

Property Taxes. Counties charge a base property tax rate of 1% on the assessed value of the property. In some counties special assessment districts exist and charge additional taxes on property including equipment, buildings, and improvements. For this study, county taxes are calculated as 1% of the average value of the property. Average value equals new cost plus salvage value divided by 2 on a per acre basis.

Insurance. Insurance for farm investments varies depending on the assets included and the amount of coverage. Property insurance provides coverage for property loss and is charged at 0.767% of the average value of the assets over their useful life. Liability insurance covers accidents on the farm and costs \$1,405 for the entire farm.

Crop Insurance. The grower, to protect the farm from crop losses, purchases crop insurance. Several levels of coverage are available, but the premium as calculated by a crop insurance agency for baby lima beans at the 75% level costs the San Joaquin County grower \$56.47 per acre. The premium cost includes the base premium less the subsidized premium amount.

Office Expense. Office and business expenses are estimated at \$50 per acre. These expenses include office supplies, telephones, bookkeeping, accounting, legal fees, shop and office utilities, and miscellaneous administrative charges. The cost is a general estimate and not based on any actual data.

Land Rent. The 200 acres are rented for cash at \$200 per acre. The rented land includes the irrigation system that is maintained by the landlord. Cash rents on the county's Westside range from \$150 to \$200 per acre (2009 Trends & Leases) depending on crop, location and soil type.

Investment Repairs. Annual maintenance is calculated as two percent of the purchase price.

Non-Cash Overhead

Non-Cash overhead is calculated as the capital recovery cost for equipment and other farm investments.

Capital Recovery Costs. Capital recovery cost is the annual depreciation and interest costs for a capital investment. It is the amount of money required each year to recover the difference between the purchase price and salvage value (unrecovered capital). It is equivalent to the annual payment on a loan for the investment with the down payment equal to the discounted salvage value. This is a more complex method of calculating ownership costs than straight-line depreciation and opportunity costs, but more accurately represents the annual costs of ownership because it takes the time value of money into account (Boehlje and Eidman). The formula for the calculation of the annual capital recovery costs is $((\text{Purchase Price} - \text{Salvage Value}) \times \text{Capital Recovery Factor}) + (\text{Salvage Value} \times \text{Interest Rate})$.

Salvage Value. Salvage value is an estimate of the remaining value of an investment at the end of its useful life. For farm machinery (tractors and implements) the remaining value is a percentage of the new cost of the investment (Boehlje and Eidman). The percent remaining value is calculated from equations developed by the American Society of Agricultural Engineers (ASAE) based on equipment type and years of life. The life in years is estimated by dividing the wear out life, as given by ASAE by the annual hours of use in this operation. For other investments including irrigation systems, buildings, and miscellaneous equipment, the

value at the end of its useful life is zero. The salvage value for land is the purchase price because land does not depreciate. The purchase price and salvage value for equipment and investments are shown in the tables.

Capital Recovery Factor. Capital recovery factor is the amortization factor or annual payment whose present value at compound interest is 1. The amortization factor is a table value that corresponds to the interest rate used and the life of the machine.

Interest Rate. The interest rate of 4.75% used to calculate capital recovery cost is the suggested basic rate by a farm lending agency as of January 2010. The rate will vary depending upon loan amount and other lending agency conditions.

Buildings. The metal building(s) are constructed on a cement slab totaling 2,400 square feet and are used for shop and/or storage.

Tools. This includes shop tools, hand tools, and miscellaneous field tools. The tools are an estimated value and not taken from any specific data.

Siphon Tubes. It is assumed the grower owns 720, 2-inch siphon tubes for use on the ranch.

Fuel Tanks. Two 300-gallon fuel tanks using gravity feed are on metal stands. The tanks are setup in a cement containment pad that meets federal, state, and county regulations.

Land Values. Being the beans are planted on rented land, land values are not shown in this study. Cropland owned by the grower in the northern San Joaquin Valley (San Joaquin County's Westside) ranges in value from \$8,000 to \$12,000 per acre (2009 Trends & Leases).

Equipment. Farm equipment is purchased new or used, but the study shows the current purchase price for new equipment. The new purchase price is adjusted to 60% to indicate a mix of new and used equipment. Annual ownership costs for equipment and other investments are shown in the Whole Farm Annual Equipment, Investment, and Business Overhead Costs table. Equipment costs are composed of three parts: non-cash overhead, cash overhead, and operating costs. Both of the overhead factors have been discussed in previous sections. The operating costs consist of repairs, fuel, and lubrication and are discussed under operating costs.

Table Values. Due to rounding, the totals may be slightly different from the sum of the components.
